# Robust PCA for High-Dimensional Data

Huan Xu, Constantine Caramanis and Shie Mannor

Talk by Shie Mannor, The Technion Department of Electrical Engineering

June 2010

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

Thank you for staying for the graveyard session

# PCA - in Words

- Observe high-dimensional points
- Find least-square-error subspace approximation
- Many applications in feature-extraction and compression

(ロ) (同) (三) (三) (三) (○) (○)

- data analysis
- communication theory
- pattern recognition
- image processing

Observe points:  $\mathbf{y} = A\mathbf{x} + \mathbf{v}$ .

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ ─臣 ─のへで

Observe points:  $\mathbf{y} = A\mathbf{x} + \mathbf{v}$ .

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ ─臣 ─のへで

Observe points:  $\mathbf{y} = A\mathbf{x} + \mathbf{v}$ .

Observe points:  $\mathbf{y} = A\mathbf{x} + \mathbf{v}$ .

▲□ > ▲圖 > ▲ 画 > ▲ 画 > → 画 → のへで

Observe points:  $\mathbf{y} = A\mathbf{x} + \mathbf{v}$ .

Goal: Find least-square-error subspace approximation.

# PCA - in Math

- Least-square-error subspace approximation
- How: Singular value decomposition (SVD) performs eigenvector decomposition of the sample-covariance matrix

(ロ) (同) (三) (三) (三) (○) (○)

# PCA - in Math

- Least-square-error subspace approximation
- How: Singular value decomposition (SVD) performs eigenvector decomposition of the sample-covariance matrix

(ロ) (同) (三) (三) (三) (○) (○)

- Magic of SVD: solving a non-convex problem
- Cannot replace quadratic objective here.

# PCA - in Math

- Least-square-error subspace approximation
- How: Singular value decomposition (SVD) performs eigenvector decomposition of the sample-covariance matrix
- Magic of SVD: solving a non-convex problem
- Cannot replace quadratic objective here.
- Consequence: Sensitive to outliers
  - Even one outlier can make the output arbitrarily skewed;

(ロ) (同) (三) (三) (三) (○) (○)

• What about a constant fraction of "outliers"?

# This Talk: High Dimensions and Corruption

#### Two key differences to pictures shown

(A) High-dimensional regime: # observations  $\leq$  dimensionality.

(ロ) (同) (三) (三) (三) (○) (○)

(B) A constant fraction of points arbitrarily corrupted.

# Outline

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

#### 1. Motivation: PCA, High dimensions, corruption

- 2. Where things get tricky: usual tools fail
- 3. HR-PCA: the algorithm
- 4. The Proof Ideas (and some details)
- 5. Conclusion

- What is high-dimensional data: #dimensionality ≈# observations.
- Why high-dimensional data analysis:
  - Many practical examples: DNA microarray, financial data, semantic indexing, images, etc

Figure: MicroArray: 24,401 dim.

・ロ ・ ・ 一 ・ ・ 日 ・ ・ 日 ・

- What is high-dimensional data: #dimensionality ≈# observations.
- Why high-dimensional data analysis:
  - Many practical examples: DNA microarray, financial data, semantic indexing, images, etc
  - Networks: user-behavior-aware network algorithms (Cognitive Networks)?

Figure: MicroArray: 24, 401 dim.

・ロト ・四ト ・ヨト ・ヨト

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

# **Corrupted Data**

#### Figure: No Outliers

Figure: With Outliers

<ロ> (四) (四) (三) (三) (三) (三)

# **Corrupted Data**

Figure: No Outliers

Figure: With Outliers

- Some observations about the corrupted points:
  - They have a large magnitude.
  - They have a large (Mahalanobis) distance.
  - They increase the volume of the smallest containing ellipsoid.

# **Corrupted Data**

#### Figure: No Outliers

Figure: With Outliers

- Some observations about the corrupted points:
  - They have a large magnitude.
  - They have a large (Mahalanobis) distance.
  - They increase the volume of the smallest containing ellipsoid.

# Our Goal: Robust PCA

- Want robustness to arbitrarily corrupted data.
- One measure: Breakdown point
- Instead: bounded error measure between true PCs and output PCs.

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

- Bound will depend on:
  - Fraction of outliers.
  - Tails of true distribution.

• "Authentic Samples"  $\mathbf{z}_1, \cdots, \mathbf{z}_t \in \mathbb{R}^m$ :  $\mathbf{z}_i = A\mathbf{x}_i + \mathbf{n}_i$ ,

- 1. Motivation
- 2. Where things get tricky
- 3. HR-PCA: the algorithm
- 4. The Proof Ideas (and some details)
- 5. Conclusion

## Features of the High Dimensional regime

- Noise Explosion in High Dimensions: noise magnitude scales faster than the signal noise;
- SNR goes to zero
  - If n ~ N(0, I<sub>m</sub>), then E||n||<sub>2</sub> = √m, with very sharp concentration.
  - Meanwhile:  $\mathbf{E}||Ax||_2 \leq \sigma \sqrt{d}$ .
- Consequences:
  - Magnitude of true samples may be much bigger than outlier magnitude.
  - The direction of each sample will be approximately orthogonal to the direction of the signal;

#### Figure: Recall low-dimensional regime

3

- Some approaches that will not work:
- Leave-one-out (more generally, subsample, compare):
  - Either sample size very small: problem

or

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

Have many corrupted points in each subsample: problem

- Some approaches that will not work:
- Leave-one-out (more generally, subsample, compare):
  - Either sample size very small: problem

or

- Have many corrupted points in each subsample: problem
- Standard Robust PCA: PCA on a robust estimation of the covariance
  - Consistency requires #(observations) >> #(dimension)
  - Not enough observations in high-dimensional case

- Some more approaches that will not work:
- · Removing points with large magnitude

- Some more approaches that will not work:
- · Removing points with large magnitude

・ コット (雪) ( 小田) ( コット 日)
- Some more approaches that will not work:
- · Removing points with large magnitude

- Some more approaches that will not work:
- Removing points with large magnitude
- Remove points with large Mahalanobis distance
  - Same example: All  $\lambda n$  corrupted points: aligned, length  $O(\sigma) << \sqrt{m}$ .

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

- Very large impact on PCA output.
- But: Mahalanobis distance of outliers very small.

- Some more approaches that will not work:
- Removing points with large magnitude

- Remove points with large Mahalanobis distance
  - Same example: All λn corrupted points: aligned, length *O*(σ) << √m.
     </li>
  - Very large impact on PCA output.
  - But: Mahalanobis distance of outliers very small.
- Remove points with large Stahel-Donoho distance

$$u_{i} \triangleq \sup_{\|\mathbf{w}\|=1} \frac{|\mathbf{w}^{\top}\mathbf{y}_{i} - \operatorname{med}_{j}(\mathbf{w}^{\top}\mathbf{y}_{j})|}{\operatorname{med}_{k}|\mathbf{w}^{\top}\mathbf{y}_{k} - \operatorname{med}_{j}(\mathbf{w}^{\top}\mathbf{y}_{j})|}.$$

 Same example: impact large, but Stahel-Donoho outlyingness small.

- For these reasons: Some robust covariance estimators have breakdown point = O(1/m), *m* = dimensions.
  - M-estimator,
  - Convex peeling, Ellipsoidal Peeling,
  - Classical outlier rejection
  - Iterative deletion, iterative trimming,
  - and others...
- These approaches cannot work in high-dimensional regime.

- 1. Motivation
- 2. Where things get tricky

#### 3. HR-PCA: the algorithm

- 4. The Proof Ideas (and some details)
- 5. Conclusion

# High-dimensional Robust PCA: Main Idea

- Get candidate directions from standard PCA (get **w**).
- Project, and use a robust variance estimator: variance of points nearer origin.

(日) (日) (日) (日) (日) (日) (日)

- Outliers can be near origin. But: impact controlled.
- Random removal of "strange" points.

# High-dimensional Robust PCA: Main Idea

- Get candidate directions from standard PCA (get **w**).
- Project, and use a robust variance estimator: variance of points nearer origin.
  - Outliers can be near origin. But: impact controlled.
- Random removal of "strange" points.
- Desired properties of an algorithm:
  - Tractable (same complexity as standard PCA);
  - Robust to outliers: performance guarantees;
  - Asymptotically optimal: t = o(n) perfect recovery.

(日) (日) (日) (日) (日) (日) (日)

Easily kernelizable;

## **Problem Setup**

- "Authentic Samples"  $\mathbf{z}_1, \cdots, \mathbf{z}_t \in \mathbb{R}^m$ :  $\mathbf{z}_i = A\mathbf{x}_i + \mathbf{n}_i$ ,
  - $\mathbf{X}_i \in \mathbb{R}^d$ .  $\mathbf{X}_i \sim \mu$ ,
  - $\mathbf{n}_i \in \mathbb{R}^m_i$ .  $\mathbf{n}_i \sim \mathcal{N}(\mathbf{0}, I_m)$ ,
  - $A \in \mathbb{R}^{d \times m}$  and  $\mu$  unknown.  $\mu$  mean zero, covariance *I*.
- The "Outliers"  $\mathbf{o}_1, \cdots, \mathbf{o}_{n-t} \in \mathbb{R}^m$ : generated arbitrarily.
- Observe:  $\mathcal{Y} \triangleq \{\mathbf{y}_1 \cdots, \mathbf{y}_n\} = \{\mathbf{z}_1, \cdots, \mathbf{z}_t\} \bigcup \{\mathbf{o}_1, \cdots, \mathbf{o}_{n-t}\}.$
- Assumptions:
  - *n*, *m* scale to infinity together;
  - $\sigma = ||A^{\top}A||$  "big" (scales to infinity slowly);
  - *µ*: spherically symmetric; abs continuous; exponential tails.

#### **Objective & Performance Measurement**

• For output PCs  $\mathbf{w}_1, \cdots, \mathbf{w}_d$ , "Expressed Variance" w.r.t.  $\mathbf{w}_1^{\text{true}}, \cdots, \mathbf{w}_d^{\text{true}}$ 

$$E_V(\mathbf{w}_1,\cdots,\mathbf{w}_d) \triangleq \frac{\sum_{i=1}^d \mathbf{w}_i^\top A A^\top \mathbf{w}_i}{\sum_{i=1}^d (\mathbf{w}_i^{\text{true}})^\top A A^\top \mathbf{w}_i^{\text{true}}} \leq 1.$$

•  $E_V = 1$  if the subspace spanned by true PCs is recovered.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

• For 
$$d = 1$$
,  $E_V(\mathbf{w}_1) = \cos^2(\angle \mathbf{w}_1, \mathbf{w}_1^{\text{true}})$ .

#### A Robust Variance Estimator

• Robust Variance Estimator:  $\overline{V}_{\hat{t}}(\mathbf{w}) \triangleq \frac{1}{n} \sum_{i=1}^{\bar{t}} |\mathbf{w}^{\top} \mathbf{y}|_{(i)}^2$ .

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

- Order statistics:  $\alpha_1, \ldots, \alpha_n \in \mathbb{R}$ , then  $\alpha_{(1)} \leq \alpha_{(2)} \leq \cdots \leq \alpha_{(n)}$ .
- Idea: If outliers small, their impact is controlled.

# The HR-PCA Algorithm

- (1) Perform PCA on empirical covariance.
- (2) If robust variance estimate in PC directions highest yet, record it, and PCs.
- (3) Randomly remove a point in proportion to its variance along PCs.

(ロ) (同) (三) (三) (三) (○) (○)

- (4) Repeat until "enough" points removed.
- (5) Output the last PCs recorded.

## The HR-PCA Algorithm

(1) Perform PCA on empirical covariance:  $\{\mathbf{w}_1, \dots, \mathbf{w}_d\}$ .

- (2) Compute  $\mathfrak{b} = RVE(\{\mathbf{w}_1, \dots, \mathbf{w}_d\})$ . If  $\mathfrak{b} > \mathfrak{b}^*$ ,
  - Update b<sup>\*</sup> = b
  - Update  $\{\mathbf{w}_1^*, \dots, \mathbf{w}_d^*\} = \{\mathbf{w}_1, \dots, \mathbf{w}_d\}.$
- (3) Randomly remove a point in proportion to its variance along PCs.

A D F A 同 F A E F A E F A Q A

- (4) Repeat until all points removed.
- (5) Output the last PCs recorded:  $\{\mathbf{w}_1^*, \dots, \mathbf{w}_d^*\}$ .

## The HR-PCA Algorithm: Pitfalls

# The HR-PCA Algorithm: Pitfalls

- Things that can go wrong:
- \* Remove authentic points
- \* May not ultimately report "best outcome."
- \* Corrupted points may contribute to ultimately reported PCs.

(ロ) (同) (三) (三) (三) (○) (○)

## The HR-PCA Algorithm: Pitfalls

- Things that can go wrong:
- \* Remove authentic points
- \* May not ultimately report "best outcome."
- \* Corrupted points may contribute to ultimately reported PCs.
- But: we show the error due to all such factors is controlled.

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

#### The Guarantees: Finite Sample + Asymptotic

- Results will depend on:
  - Fraction of outliers: λ.
  - Tails of  $\mu$ .
- Define:  $\mathcal{V}:[0,1] \rightarrow [0,1]$

$$\mathcal{V}(\alpha) = \int_{-c_{\alpha}}^{c_{\alpha}} x^2 \overline{\mu}(dx).$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

#### The Guarantees: Finite Sample + Asymptotic

**Theorem**: The following holds in probability ( $n, m, \sigma$  scale):

$$\text{E.V.(output)} \geq \max_{\kappa} \left[ \frac{\mathcal{V}\left(1 - \frac{\lambda^*(1+\kappa)}{(1-\lambda^*)\kappa}\right)}{(1+\kappa)} \right] \times \left[ \frac{\mathcal{V}\left(\frac{\hat{t}}{t} - \frac{\lambda^*}{1-\lambda^*}\right)}{\mathcal{V}\left(\frac{\hat{t}}{t}\right)} \right].$$

◆□▶ ◆□▶ ◆ □▶ ◆ □▶ ─ □ ─ の < @

## The Guarantees: Finite Sample + Asymptotic

**Theorem**: The following holds in probability  $(n, m, \sigma \text{ scale})$ :

$$\text{E.V.(output)} \geq \max_{\kappa} \left[ \frac{\mathcal{V}\left(1 - \frac{\lambda^*(1+\kappa)}{(1-\lambda^*)\kappa}\right)}{(1+\kappa)} \right] \times \left[ \frac{\mathcal{V}\left(\frac{\hat{t}}{t} - \frac{\lambda^*}{1-\lambda^*}\right)}{\mathcal{V}\left(\frac{\hat{t}}{t}\right)} \right]$$

- The Bound:
  - Term 1: May not remove all outliers, and some authentic points may be removed.
  - Term 2: May have small outliers that alter PC directions.

A D F A 同 F A E F A E F A Q A

- If t = o(n), RHS = 1: optimal recovery.
- Breakdown point: 1/2.

## Asymptotic Performance Guarantee

#### E.V. is lower bounded by

If the *proportion* of outliers goes to zero: the Expressed Variance equals 1.

# **Proof Idea**

- (1) "Blessing of dimensionality": empirical covariance estimates good, even for high-dimensional regime;
- (2) Random removal: have a "good" solution, or outlier is removed with large probability;
- (3) Therefore: at some early iteration, algorithm finds a "good" solution.
- (4) Output of algorithm has higher robust variance estimate than the "good" solution. We show output must then also be (almost as) "good."

With high probability:

(1.a) Largest eigenvalue of the empirical noise covariance matrix is bounded:

$$\sup_{\mathbf{w}\in\mathcal{S}_m}\frac{1}{n}\sum_{i=1}^t(\mathbf{w}^{\top}\mathbf{n}_i)^2\leq c.$$

(1.b) Largest eigenvalue of the signals in original space converges to 1:

$$\sup_{\mathbf{w}\in\mathcal{S}_d} |\frac{1}{t}\sum_{i=1}^t (\mathbf{w}^\top \mathbf{x}_i)^2 - 1| \leq \epsilon.$$

(日) (日) (日) (日) (日) (日) (日)

(1.c) RVE is a valid variance estimator for the *d*-dimensional signals **x**:

$$\sup_{\mathbf{w}\in\mathcal{S}_d} \big| \frac{1}{t} \sum_{i=1}^{\hat{t}} |\mathbf{w}^\top \mathbf{x}|_{(i)}^2 - \mathcal{V}\left(\frac{\hat{t}}{t}\right) \big| \leq \epsilon.$$

(1.d) RVE is a valid estimator of the variance of the authentic samples,  $\mathbf{z} = A\mathbf{x} + \mathbf{n}$ : uniformly over all  $\mathbf{w} \in S_m$ ,

$$(1-\epsilon) \|\mathbf{w}^{\top} A\|^{2} \mathcal{V}\left(\frac{t'}{t}\right) - c \|\mathbf{w}^{\top} A\| \leq \frac{1}{t} \sum_{i=1}^{t'} \|\mathbf{w}^{\top} \mathbf{z}\|_{(i)}^{2} \leq (1+\epsilon) \|\mathbf{w}^{\top} A\|^{2} \mathcal{V}\left(\frac{t'}{t}\right) + c \|\mathbf{w}^{\top} A\|.$$

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

#### Proof - Step 1.a - details

(1.a) Largest eigenvalue of the variance of noise matrix is bounded:

۱

$$\sup_{\boldsymbol{\mathsf{N}}\in\mathcal{S}_m}\frac{1}{n}\sum_{i=1}^t(\boldsymbol{\mathsf{w}}^\top\boldsymbol{\mathsf{n}}_i)^2\leq c.$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

• Two keys: "blessing of dimensionality" and uniform laws of large numbers.

## Proof - Step 1.a - details

(1.a) Largest eigenvalue of the variance of noise matrix is bounded:

$$\sup_{\mathbf{w}\in\mathcal{S}_m}\frac{1}{n}\sum_{i=1}^t(\mathbf{w}^{\top}\mathbf{n}_i)^2\leq c.$$

- Two keys: "blessing of dimensionality" and uniform laws of large numbers.
- Step 1 (a): Need basic Lemma:
- Lemma: For  $\Gamma$  a  $m \times t$  matrix ( $m \le t$ ),  $\Gamma_{ij} \sim \mathcal{N}(0, 1)$ , i.i.d.:

$$\Pr(\sigma_{\max}(\Gamma) > \sqrt{m} + \sqrt{t} + \sqrt{t}\epsilon) \le \exp(-t\epsilon^2/2).$$

(日) (日) (日) (日) (日) (日) (日)

## Proof - Step 1.a - details

(1.a) Largest eigenvalue of the variance of noise matrix is bounded:

$$\sup_{\mathbf{w}\in\mathcal{S}_m}\frac{1}{n}\sum_{i=1}^t(\mathbf{w}^{\top}\mathbf{n}_i)^2\leq c.$$

- Two keys: "blessing of dimensionality" and uniform laws of large numbers.
- Step 1 (a): Need basic Lemma:
- Lemma: For  $\Gamma$  a  $m \times t$  matrix ( $m \le t$ ),  $\Gamma_{ij} \sim \mathcal{N}(0, 1)$ , i.i.d.:

$$\Pr(\sigma_{\max}(\Gamma) > \sqrt{m} + \sqrt{t} + \sqrt{t}\epsilon) \le \exp(-t\epsilon^2/2).$$

Observation:

$$\sup_{\mathbf{w}\in\mathcal{S}_m}\frac{1}{t}\sum_{i=1}^t (\mathbf{w}^{\top}\mathbf{n}_i)^2 = \lambda_{\max}(\Gamma\Gamma^{\top})/t = \sigma_{\max}^2(\Gamma)/t.$$

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

### Proof - Step 1.a - An Aside

- Where do these results come from:
- Basic idea: dimension-free concentration of measure
- **Theorem**: Let *F* be *L*-Lipschitz w.r.t. Euclidean norm,  $X \sim N(0, I)$  standard Gaussian measure.  $M_F$  the mean of F(X). Then

$$\mathbb{P}(F(X) \geq M_F + \xi) \leq e^{-\xi^2/2L^2}.$$

- Basic observation:  $\sigma_{\max}(\cdot) : \mathbb{R}^{n_1 \times n_2} \longrightarrow \mathbb{R}$  is 1-Lipschitz.
- Two nice references: (a) Davidson and Szarek: Operators, Random Matrices & Banach Spaces; (b) Matousek: Lectures on Discrete Geometry.

# **Proof Idea**

- (1) "Blessing of dimensionality": empirical covariance estimates good, even for high-dimensional regime;
- (2) Random removal: have a "good" solution, or outlier is removed with large probability;
- (3) Therefore: at some early iteration, algorithm finds a "good" solution.
- (4) Output of algorithm has higher robust variance estimate than the "good" solution. We show output must then also be (almost as) "good."

variance of authentic pts

- This means: variance on the direction of found PCs is mostly due to the authentic samples.
- Hence:  $\{\mathbf{w}_1, \ldots, \mathbf{w}_d\}$  must be close to true PCs.
- Theorem: If *G<sup>c</sup>(s)* step *s* is not good then next point removed is an outlier with probability at least <sup>κ</sup>/<sub>1+κ</sub>.

# **Proof Idea**

- (1) "Blessing of dimensionality": empirical covariance estimates good, even for high-dimensional regime;
- (2) Random removal: have a "good" solution, or outlier is removed with large probability;
- (3) Therefore: at some early iteration, algorithm finds a "good" solution.
- (4) Output of algorithm has higher robust variance estimate than the "good" solution. We show output must then also be (almost as) "good."

 Theorem: With high probability, we have a "good event" by time at most s<sub>0</sub> > λn[(1 + κ)/κ].

- Theorem: With high probability, we have a "good event" by time at most s<sub>0</sub> > λn[(1 + κ)/κ].
- Intuition: Suppose subsequent steps were independent.
  - Since, "expected number of corrupted points removed each step" is κ/(1 + κ).
  - After M steps, expected corrupted points removed is M<sup>κ</sup>/<sub>1+κ</sub>.
  - Therefore: All the outliers removed after  $M = \lambda n \frac{1+\kappa}{\kappa} (1+\varepsilon)$  steps, with exponentially high probability.

(日) (日) (日) (日) (日) (日) (日)

- Theorem: With high probability, we have a "good event" by time at most s<sub>0</sub> > λn[(1 + κ)/κ].
- Intuition: Suppose subsequent steps were independent.
  - Since, "expected number of corrupted points removed each step" is κ/(1 + κ).
  - After M steps, expected corrupted points removed is M<sup>κ</sup>/<sub>1+κ</sub>.
  - Therefore: All the outliers removed after  $M = \lambda n \frac{1+\kappa}{\kappa} (1+\varepsilon)$  steps, with exponentially high probability.
  - The Problem: not i.i.d.
  - The Fix: use martingales and Azuma-Hoeffding.

• Let  $T = \min\{s | \mathcal{G}(s) \text{ is true}\}.$ 

- Let  $T = \min\{s | \mathcal{G}(s) \text{ is true}\}.$
- Define the random variable (w.r.t. natural filtration  $\mathcal{F}_s$ ):

$$X_{s} = \begin{cases} |\mathcal{O}(T-1)| + \frac{\kappa}{1+\kappa} \cdot (T-1), & \text{if } T \leq s; \\ |\mathcal{O}(s)| + \frac{\kappa}{1+\kappa} \cdot s, & \text{if } T > s. \end{cases}$$

Note:  $X_0 = \lambda n$ .

- Let  $T = \min\{s | \mathcal{G}(s) \text{ is true}\}.$
- Define the random variable (w.r.t. natural filtration  $\mathcal{F}_s$ ):

$$X_{s} = \begin{cases} |\mathcal{O}(T-1)| + \frac{\kappa}{1+\kappa} \cdot (T-1), & \text{if } T \leq s; \\ |\mathcal{O}(s)| + \frac{\kappa}{1+\kappa} \cdot s, & \text{if } T > s. \end{cases}$$

Note:  $X_0 = \lambda n$ .

• **Lemma**:  $\{X_s, \mathcal{F}_s\}$  is a supermartingale.

- Let  $T = \min\{s | \mathcal{G}(s) \text{ is true}\}.$
- Define the random variable (w.r.t. natural filtration  $\mathcal{F}_s$ ):

$$X_{s} = \begin{cases} |\mathcal{O}(T-1)| + \frac{\kappa}{1+\kappa} \cdot (T-1), & \text{if } T \leq s; \\ |\mathcal{O}(s)| + \frac{\kappa}{1+\kappa} \cdot s, & \text{if } T > s. \end{cases}$$

Note:  $X_0 = \lambda n$ .

- **Lemma**:  $\{X_s, \mathcal{F}_s\}$  is a supermartingale.
- Now we have: for  $s_0 = \lambda n[(1 + \kappa)/\kappa](1 + \varepsilon)$

$$\mathbb{P}(T > s_0) \leq \mathbb{P}\left(X_{s_0} \geq \frac{\kappa s_0}{1+\kappa}\right) = \mathbb{P}\left(X_{s_0} \geq (1+\epsilon)\lambda n\right)$$

- Let  $T = \min\{s | \mathcal{G}(s) \text{ is true}\}.$
- Define the random variable (w.r.t. natural filtration  $\mathcal{F}_s$ ):

$$X_{s} = \begin{cases} |\mathcal{O}(T-1)| + \frac{\kappa}{1+\kappa} \cdot (T-1), & \text{if } T \leq s; \\ |\mathcal{O}(s)| + \frac{\kappa}{1+\kappa} \cdot s, & \text{if } T > s. \end{cases}$$

Note:  $X_0 = \lambda n$ .

- **Lemma**:  $\{X_s, \mathcal{F}_s\}$  is a supermartingale.
- Now we have: for  $s_0 = \lambda n[(1 + \kappa)/\kappa](1 + \varepsilon)$

$$\mathbb{P}(T > s_0) \leq \mathbb{P}\left(X_{s_0} \geq \frac{\kappa s_0}{1+\kappa}\right) = \mathbb{P}\left(X_{s_0} \geq (1+\epsilon)\lambda n\right)$$

Azuma-Hoeffding completes the proof.

# **Proof Idea**

- (1) "Blessing of dimensionality": empirical covariance estimates good, even for high-dimensional regime;
- (2) Random removal: have a "good" solution, or outlier is removed with large probability;
- (3) Therefore: at some early iteration, algorithm finds a "good" solution.
- (4) Output of algorithm has higher robust variance estimate than the "good" solution. We show output must then also be (almost as) "good."

- Putting it all together:
- An early iteration produces directions ŵ<sub>1</sub>,..., ŵ<sub>d</sub> that have "most of" the variance.
- Bound quality on these directions:

$$E_V(\hat{\mathbf{w}}_1, \cdots, \hat{\mathbf{w}}_d) \triangleq \frac{\sum_{i=1}^d \hat{\mathbf{w}}_i^\top A A^\top \hat{\mathbf{w}}_i}{\sum_{i=1}^d (\mathbf{w}_i^{\text{true}})^\top A A^\top \mathbf{w}_i^{\text{true}}}$$

- The final algorithm only produces directions w<sup>\*</sup><sub>1</sub>,..., w<sup>\*</sup><sub>d</sub> with biggest robust variance estimator.
- Bound quality on these directions:

$$E_{V}(\mathbf{w}_{1}^{*},\cdots,\mathbf{w}_{d}^{*}) \triangleq \frac{\sum_{i=1}^{d} (\mathbf{w}_{i}^{*})^{\top} A A^{\top} \mathbf{w}_{i}^{*}}{\sum_{i=1}^{d} \sum_{i=1}^{d} \hat{\mathbf{w}}_{i}^{\top} A A^{\top} \hat{\mathbf{w}}_{i}}.$$

# Kernelization

- Using a kernel function k(·, ·) to represent a feature mapping ↑(·)
- PCA can be kernelized using Kernel PCA, with output in a form  $\mathbf{v}_q = \sum_{i=1}^{n-s} \alpha_i(q) \Upsilon(\hat{\mathbf{y}}_i), \quad q = 1, \cdots, d.$

(日) (日) (日) (日) (日) (日) (日)

- HR-PCA Algorithm requires:
  - Computing PCA;
  - Computing Robust Variance Estimator;
- Both steps can be done.

# Conclusion

- Methodology for handling dimensionality reduction when:
  - 1. #(Observation)  $\sim \#$ (Dimension)
  - 2. #(Outliers) is "large"
- The key idea: verify projections statistics behave in a certain way, if not probabilistic point removal
- Works well in simulations

On the todo list:

- Generalize to other identification problems with outliers: when a probabilistic model is available
- Extend to stochastic programming with corrupted sampled data
- Looking for an online algorithm.
